Psi-Bubble Propulsion

Engineering the Next Age of Space Travel

Gary Thomas Alcock

Density Field Dynamics

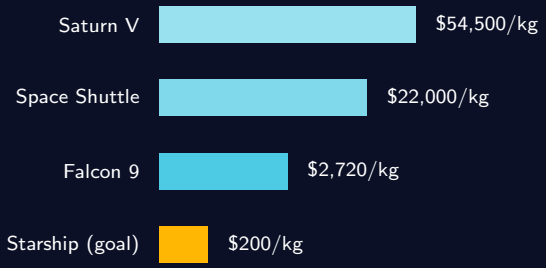
The Problem

95%

of every rocket is thrown away.

Chemical propulsion wastes nearly all its mass on propellant.

The Cost of Space Access



The Time Problem

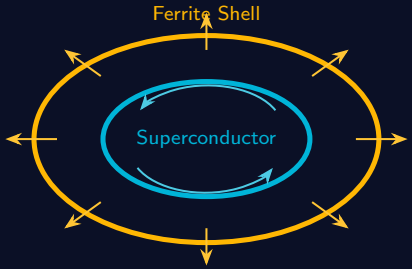
Earth to Mars (chemical):	7–9 months
Earth to Jupiter (chemical):	5–7 years
Nearest star (chemical):	80,000 years

Chemical rockets are fundamentally too slow for a spacefaring civilization.

What if you didn't need propellant at all?

A device that moves spacetime itself—no exhaust, no fuel, no reaction mass.

The Psi-Bubble Device



ψ-gradient radiates outward

How It Works

The vehicle surfs a self-generated wave in the density field.

No propellant expelled. Momentum carried by ψ-waves.

Zero g-forces at any acceleration

- Chemical rocket: crew endures 3–4 g during burns
- Ion drive: micro-g for months, muscle and bone atrophy
- Psi-bubble: spacetime itself moves—occupants in free fall

The Density Field Equation

$$\Box\psi + \frac{dV}{d\psi} = \kappa T + \lambda\left(\psi^2 - v^2\right)\psi$$

$\Box\psi$	$dV/d\psi$	κT	$\lambda(\psi^2 - v^2)\psi$
wave propagation	self-interaction	matter coupling	symmetry breaking

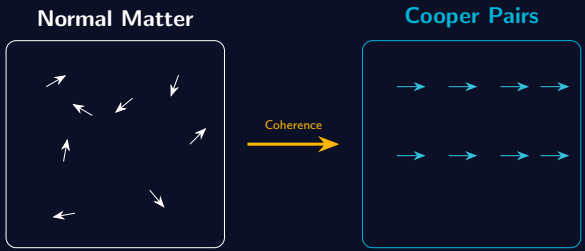
The Coupling Problem

$$10^{-44}$$

Gravity–matter coupling is absurdly weak.

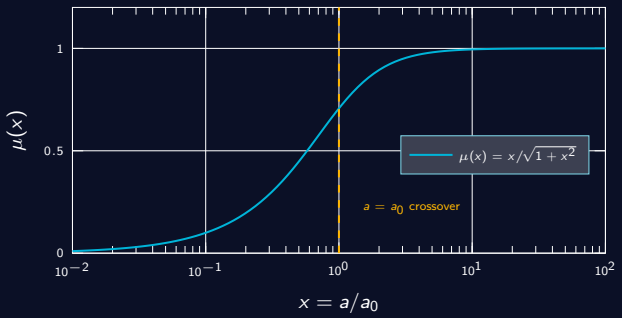
Three known amplification mechanisms close the gap.

Quantum Coherence Amplification



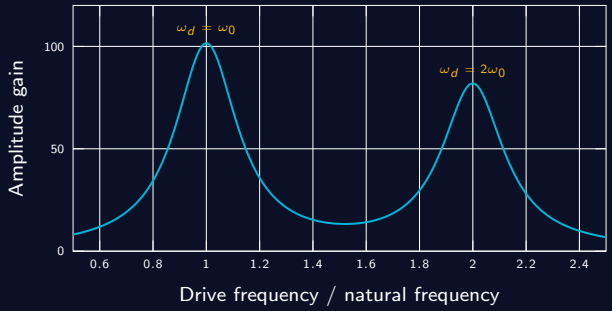
Enhancement: $N \sim 10^{20} \Rightarrow$ coupling boost $\sim 10^{20}$

MOND-Regime Enhancement



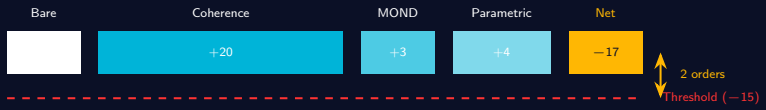
Deep space ($a \ll a_0$): 10–1000× enhancement

Parametric Resonance



Achievable gain: $5 \times 10^2 - 10^5$

Enhancement Budget



Gap: only 2 orders of magnitude—within reach of engineering optimization.

Self-Consistency Proofs

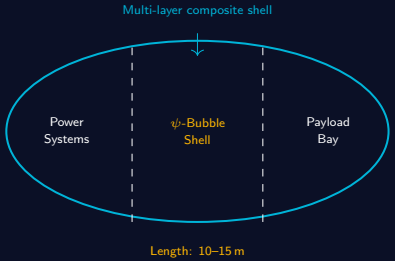
- ✓ **Convergence:** proven via fixed-point iteration
- ✓ **Stability:** Lyapunov analysis confirms bounded solutions
- ✓ **Energy conservation:** stress-energy tensor $\nabla_\mu T^{\mu\nu} = 0$
- ✓ **Momentum:** carried by ψ-waves in the density field

No exotic matter. No negative energy. No warp drive.

Breaking Spherical Symmetry

Rotation of Cooper pairs creates directional asymmetry in the ψ-gradient.

Vehicle Architecture



Prolate spheroid minimizes surface area while maximizing internal volume.

Multi-Layer Shell Construction

Outer thermal shield — 2 mm Al

Ferrite composite — 8 mm

YBCO superconductor — 3 mm

Cryogenic insulation — 5 mm

Structural carbon-fiber — 4 mm

Total wall thickness: 22 mm — 520 hexagonal tiles

Power Architecture

13 kW maintains 1 MJ stored in the ψ-field

Energy recycled each rotation cycle—no propellant consumption.

Flight Performance Comparison

Destination	Chemical	Psi-Bubble (1 g)
Earth–Moon	3 days	3.5 hours
Earth–Mars	7–9 months	2 days
Earth–Jupiter	5–7 years	6 days
Earth–Saturn	7+ years	9 days
Earth–Pluto	9+ years	18 days
Nearest star	80,000 yr	5.8 years

Continuous 1 g acceleration with zero propellant.

Vehicle Specifications

Parameter	Value
Hull diameter	8 m
Hull length	12 m
Total mass	15,000 kg
Payload fraction	75%
Shell temperature	77 K (LN_2)
Power requirement	13 kW steady-state
Max acceleration	10 g (structural limit)
Crew capacity	6–12

Three-Layer Quench Protection

Layer 1: Real-time thermal monitoring per tile

Layer 2: Active heater quench-spreading in 2 ms

Layer 3: Passive copper stabilizer dumps energy safely

Field collapse is graceful, not catastrophic—vehicle coasts safely.

Manufacturing and Cost

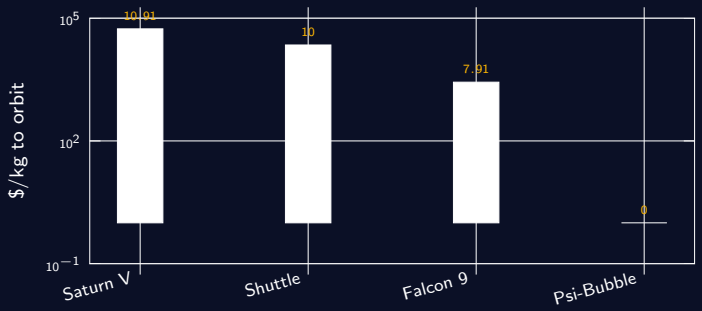
- 520 hexagonal tiles tessellate the spheroid shell
- Each tile: YBCO on ferrite substrate, cryo-rated connectors
- Prototype unit cost: $1.2–3.1B
- Production fleet cost: $130–280M per vehicle
- Learning curve: semiconductor-style yield improvement

Interstellar Capability

Destination	1 g		10 g	
	Ship	Earth	Ship	Earth
Alpha Centauri (4.4 ly)	3.6 yr	5.9 yr	1.3 yr	4.5 yr
Tau Ceti (12 ly)	5.2 yr	13.8 yr	2.0 yr	12.2 yr
Galactic center	20 yr	28 kyr	7.2 yr	27 kyr
Observable edge	48 yr	46 Gyr	5.2 yr	46 Gyr

The entire observable universe reachable in a human lifetime.

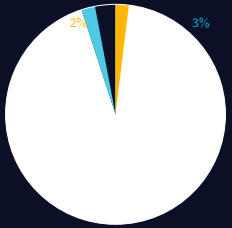
Cost Revolution



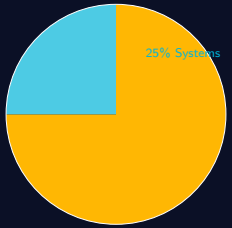
Psi-bubble: $1/kg (energy cost only, no propellant)

Payload Revolution

Chemical Rocket



Psi-Bubble



From 2% useful payload to 75%—a 37× improvement.

Market Opportunity

Market Segment	10 yr	20 yr	50 yr
Launch services	$50B	$200B	$1T
Space tourism	$10B	$100B	$500B
Asteroid mining	$5B	$500B	$10T
Interstellar probes	—	$50B	$500B
Colonization	—	$100B	$50T
Total	**$65B**	**$950B**	**$62T**

The largest addressable market in human history.

Intellectual Property Landscape

All Pais/Navy patents: **EXPIRED**

8 patentable innovations identified in DFD framework

Patent program cost: $135–240K

First-mover advantage is open—but it will not last.

Why the Musk Ecosystem

SpaceX

Launch platforms

Test infrastructure

Flight heritage

Tesla

Battery systems

Power electronics

Manufacturing

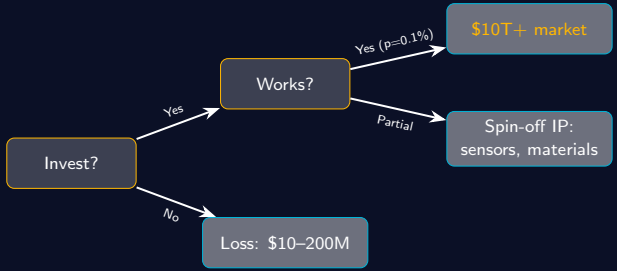
Boring Co

Tunnel boring

Underground test facilities

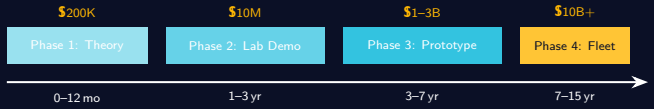
Vertical integration across all critical subsystems.

Decision Analysis



Expected value at 0.1% success: **$10B**

Development Roadmap



Decision gate at each phase—risk-managed investment.

The Ask

$200K parasitic on MAGO detector program

— or —

$10M dedicated program at SQMS

First measurement within 12 months of funding.

Key Numbers at a Glance

Parameter	Value
Bare coupling (κ)	10^{-44}
Coherence boost	10^{20}
MOND enhancement	10^{1}–10^{3}
Parametric gain	$10^{2.7}$–10^{5}
Net effective coupling	$\sim 10^{-17}$
Propulsion threshold	10^{-15}
Power requirement	13 kW
Payload fraction	75%
Cost to LEO	\$1/kg
Mars transit (1 g)	2 days

If this works, it is the most important technology in human history.

If it doesn't, you lost less than a fighter jet's landing gear.

$$\Box\psi + \frac{dV}{d\psi} = \kappa\, T + \lambda\left(\psi^2 - v^2\right)\psi$$

The door is constrained but not locked.
